Deep Learning Assignment

SMS Spam Detection using Vanilla RNN (SimpleRNN)

Objective

The objective of this assignment is to build a deep learning model that classifies SMS messages as spam or ham using a Vanilla RNN (SimpleRNN).

The project includes:

- Data cleaning and exploration
- Text preprocessing for sequence models
- Building and training a Vanilla RNN
- Evaluating performance using precision, recall, F1-score, and confusion matrix
- Improving model performance through tuning and error analysis

TASK -A PART -08

Data Summary

The SMS Spam dataset was cleaned and prepared for modeling.

Data Cleaning Steps:

- Only the relevant columns (v1 and v2) were retained.
- Columns were renamed to **label** and **text**.
- Labels were encoded as:
  - ham = 0
  - spam = 1

Dataset Shape:

- The cleaned dataset contains **5572 SMS messages** and **2 columns**.

Class Distribution:

- Ham messages: ~86.6%
- Spam messages: ~13.4%

The dataset is imbalanced, with significantly more ham messages than spam messages.

```
# TASK -B PART-01
# Train / Validation / Test Split (80/10/10 with stratification)

# Separate features and labels
X = df['text']
y = df['label']

# First split: Train (80%) and Temp (20%)
X_train, X_temp, y_train, y_temp = train_test_split(
    X,
    y,
    test_size=0.2,
    stratify=y,
    random_state=42
)

# Second split: Validation (10%) and Test (10%)
X_val, X_test, y_val, y_test = train_test_split(
    X_temp,
    y_temp,
    test_size=0.5,
    stratify=y_temp,
    random_state=42
)
```

Test samples: 558
```

TASK -B PART-03

Train / Validation / Test Split

The dataset was divided into three subsets:

- Training Set (80%) – used to train the model.
- Validation Set (10%) – used to tune model parameters and monitor performance during training.
- Test Set (10%) – used to evaluate the final model performance.

Stratified sampling was used to ensure that the proportion of spam and ham messages remains consistent across all subsets.

```
#TASK -B PART-04
#Tokenize Messages

# Define vocabulary size
vocab_size = 10000

# Create tokenizer
tokenizer = Tokenizer(num_words=vocab_size, oov_token="<OOV>")

Validation shape: (557, 100)
Test shape: (558, 100)
```

TASK -B PART-08

Preprocessing Decisions

Vocabulary Size (10,000): A vocabulary size of 10,000 was selected to capture the most frequent words in SMS messages while keeping the model computationally efficient.

Maximum Sequence Length (100): SMS messages are generally short. Padding sequences to a maximum length of 100 ensures that all input sequences have equal length for the RNN model.

Handling Unknown Words: An out-of-vocabulary token (`<OOV>`) was used so that words not present in the training vocabulary can still be represented during inference.

```
# TASK-C PART-01
# Build the Vanilla RNN Model

TASK-C PART-08

Training Observations

The Vanilla RNN model was trained using an embedding layer, a SimpleRNN layer, dropout, and a sigmoid output layer.

The training curves show that:

- Training accuracy steadily increased across epochs.
- Validation accuracy improved initially and then stabilized.
- Training loss decreased as the model learned meaningful patterns from SMS messages.

Early stopping helps prevent overfitting by stopping training when validation performance stops improving.

```
# TASK-D PART-01

TASK-D PART-05

Error Analysis

Five misclassified SMS messages were analyzed to understand model limitations. Some spam messages were classified as ham because they contained informal or conversational language that resembles normal messages. These are considered **false negatives**.

Some legitimate messages were classified as spam due to unusual wording or very short message length, which provides limited context for the model.

In real-world spam detection systems, **false negatives (spam classified as ham)** are more problematic because spam messages that reach users may contain scams, phishing links, or malicious content.

Therefore, minimizing false negatives is an important goal when improving spam detection systems.

TASK-E — PART-01 Improve the Model

Model Improvements

In this section, the baseline model is compared with an improved model.

The baseline model used:

- Vocabulary size = 10,000
- Maximum sequence length = 100
- SimpleRNN units = 64
- Dropout = 0.5

To improve model performance, two enhancements were applied:

1. Increased the **maximum sequence length** from 100 to 150.
2. Increased the **number of SimpleRNN units** from 64 to 128.

These improvements allow the model to capture longer SMS context and learn richer sequence representations.

```
# TASK-E PART-02
# Improvement 1- Increase Sequence Length

# Improved maximum sequence length
max_len_improved = 150

# Pad sequences again with new length
X_train_pad_imp = pad_sequences(X_train_seq, maxlen=max_len_improved, padding='post')
X_val_pad_imp = pad_sequences(X_val_seq, maxlen=max_len_improved, padding='post')
X_test_pad_imp = pad_sequences(X_test_seq, maxlen=max_len_improved, padding='post')
```

```
# TASK-E PART-03
# Improvement 2- Build Improved Model -SimpleRNN(128) from SimpleRNN(64)
model_improved = Sequential([

    Embedding(input_dim=vocab_size, output_dim=embedding_dim),

Start coding or generate with AI.

TASK-E PART-07

Baseline vs Improved Model Comparison

Model	Accuracy	Precision (Spam)	Recall (Spam)	F1-score (Spam)
Baseline RNN	~0.92	~0.90	~0.68	~0.77
Improved RNN	0.87	0.00	0.00	0.00

The improved model increased sequence length and RNN units. However, due to dataset imbalance, the model became biased toward predicting the majority class (ham). As a result, spam messages were not correctly detected.

This highlights the importance of handling class imbalance when improving machine learning models.

Baseline model was actually better-improvements do not always outperform the baseline

TASK-E PART-08

Conclusion

In this assignment, a Vanilla RNN model was developed to classify SMS messages as spam or ham.

The baseline model used an embedding layer, a SimpleRNN layer with 64 units, dropout, and a sigmoid output layer. This model achieved strong performance with approximately 92% accuracy and good spam detection capability.

To improve the model, two enhancements were applied:

1. Increasing the maximum sequence length from 100 to 150.
2. Increasing the number of SimpleRNN units from 64 to 128.

Although the improved model increased model capacity, it became biased toward the majority class (ham) due to dataset imbalance.
